Project Overview

Our project focuses on improving the course registration system for students. Many students experience difficulties when trying to find available courses and register for the next semester. In our experience, the current student website is confusing and not very organized. Sometimes it is hard to find the full list of courses or understand which courses we are allowed to take.

Another problem is that students often need to meet with an academic advisor just to understand which classes they should register for. This process can take time and can slow down registration. Because of these issues, our team decided to design a system that makes course registration easier and more automated.

Our goal is to create a system where students can easily see available courses, understand which classes they can take, and register for them without unnecessary steps.

1. Odoo Module Mapping

To implement the AutoEnroll AI system, the team analyzed available Odoo modules and mapped them to the core system requirements. The goal is to use existing enterprise tools whenever possible rather than building new software from scratch.

System Requirement	Odoo Module	Reason for Selection
Student profile management	Contacts	The Contacts module can store student information such as name, email, and academic details.
Course schedule planning	Calendar	The Calendar module allows students to view and manage course schedules and detect time conflicts.
Student communication and notifications	Discuss	The Discuss module supports messaging and notifications between users.
Course documents and resources	Documents	The Documents module allows storage and access to course-related files and academic information.
Task tracking for registration workflow	Project	The Project module can be used to manage registration tasks and planning steps.

These modules were selected because they align with the key system requirements identified in the previous requirements document and can support the core functionality of the proposed system.

2. Configuration vs Customization Decisions

Enterprise systems typically prioritize configuration of existing tools rather than building new custom software. For this project, the team plans to configure existing Odoo modules to demonstrate the system concept.

Configuration (Planned)

The team plans to configure the following Odoo modules:

- **Contacts** module to store and manage student profiles
- **Calendar** module to manage course schedules
- **Discuss** module to provide notifications and communication
- **Documents** module to store course materials and information
- **Project** module to represent registration planning steps

These modules will be configured to simulate the workflow of a student planning their course schedule.

Customization (Not Planned)

The team will intentionally avoid building complex custom functionality, including:

- Development of a full AI scheduling algorithm
- Integration with a real university student database
- Creation of new custom Odoo modules through programming

Instead, the focus will be on demonstrating how existing enterprise tools can support the proposed system concept.

3. Hero Prototype Definition

The hero prototype for Week 8 will demonstrate a simplified **student course planning workflow**.

Prototype Workflow

The prototype will demonstrate the following steps:

1. A student profile is created in the **Contacts** module.
2. Course schedules are represented using the **Calendar** module.
3. The student selects and views potential courses for a semester.
4. The system identifies scheduling conflicts through the calendar view.
5. Notifications or messages are delivered through the **Discuss** module.

Why This Prototype Demonstrates System Value

This prototype demonstrates the core value of the AutoEnroll AI system by showing how students can plan their course schedules more efficiently and avoid scheduling conflicts. It addresses the main problem identified earlier in the project: students struggling with course registration and academic planning.

By combining several Odoo modules into one workflow, the prototype illustrates how enterprise systems can integrate multiple tools to support user needs and simplify complex processes.
